## Positronium and its hyperfine structure (HFS)

### Positronium (Ps)

The bound state of an electron ( $e^-$ ) and a positron ( $e^+$ )

orthopositronium (o-Ps)  $\cdots 1^3S_1$  mostly 3  $\gamma$  decay  
parapositronium (p-Ps)  $\cdots 1^1S_0$  mostly 2  $\gamma$  decay

### Hyperfine structure (HFS)

- The energy splitting between o-Ps and p-Ps
- The value of the HFS

#### Experimental average

**203.388 65(67) GHz (3.3 ppm)**

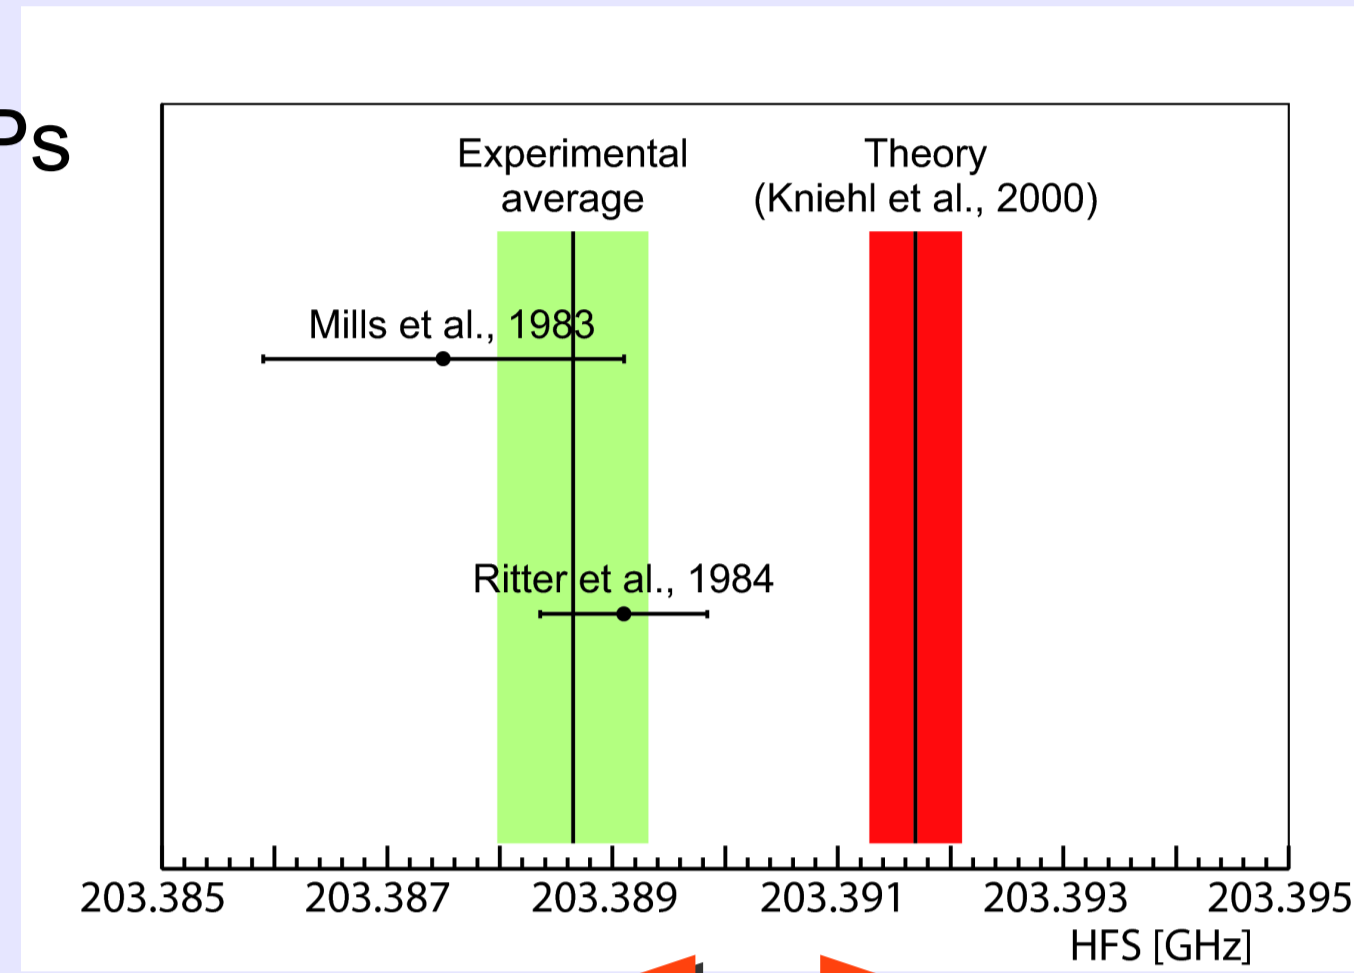

PRA 27, 262 (1983)  
PRA 30, 1331 (1984)

#### Theory

**203.391 69(41) GHz (2.0 ppm)**

PRL 85, 5094 (2000)

- The measured values are **consistent with each other** and **lower than the theoretical calculation**.

**15 ppm (3.9  $\sigma$ ) discrepancy**

## Measurement using the Zeeman effect

### How to measure the HFS? Induce the transition

- In a static magnetic field, energy levels of o-Ps split between  $m_z=0$  and  $m_z=\pm 1$  states. (Zeeman Effect)  $\rightarrow$  2  $\gamma$  decay rate increases.
- At about **9 kG**,  $\Delta_{\text{mix}}$  is about **3 GHz (microwave)**.
- The HFS value is **calculated from  $\Delta_{\text{mix}}$** . (*indirect measurement*)
- What about direct measurement?  
 $\rightarrow$  See T. Suehara's poster (Mo195)

### Common systematic uncertainties in the previous experiments

#### 1. Underestimation of material effects

- Unthermalized o-Ps can have a significant effect (especially at low material density).  $\leftarrow$  o-Ps lifetime puzzle (1990's)

#### 2. Non-uniformity of the magnetic field

- It is quite difficult to get ppm level uniform field in a large Ps creation volume

## Experimental setup

To **reduce these systematic uncertainties**, we use the following **new methods**.

### Large bore superconducting magnet

- Operated in **Persistent Current mode** (stable).
- **70 ppm magnetic field uniformity** without any compensations.

Waveguide

**2.853 GHz**  
**500 W CW RF**  
(GaN Amplifier)

80 cm

RF Cavity  
 $f_0 = 2.853 \text{ GHz}$   
 $Q = 14700 \pm 50$   
TM<sub>110</sub> mode  
Filled with  
1.5 atm gas  
(90% N<sub>2</sub> +  
10% iso-C<sub>4</sub>H<sub>10</sub>)

### High performance gamma-ray detectors

**LaBr<sub>3</sub> (Ce) scintillators** (x 6)  
1.5" in diameter & 2.0" long

**High energy and timing resolutions,**  
**short decay constant**

## Time information

- Plastic scintillator is used to **tag emitted  $\beta^+$** .
- Get the time information between o-Ps creation ( $t=0$ ) and decay.
- (1) We can measure the thermalization.**
- (2) Prompt suppression**

0.2 mm thick, 15 mm x 15 mm  
Plastic Scintillator

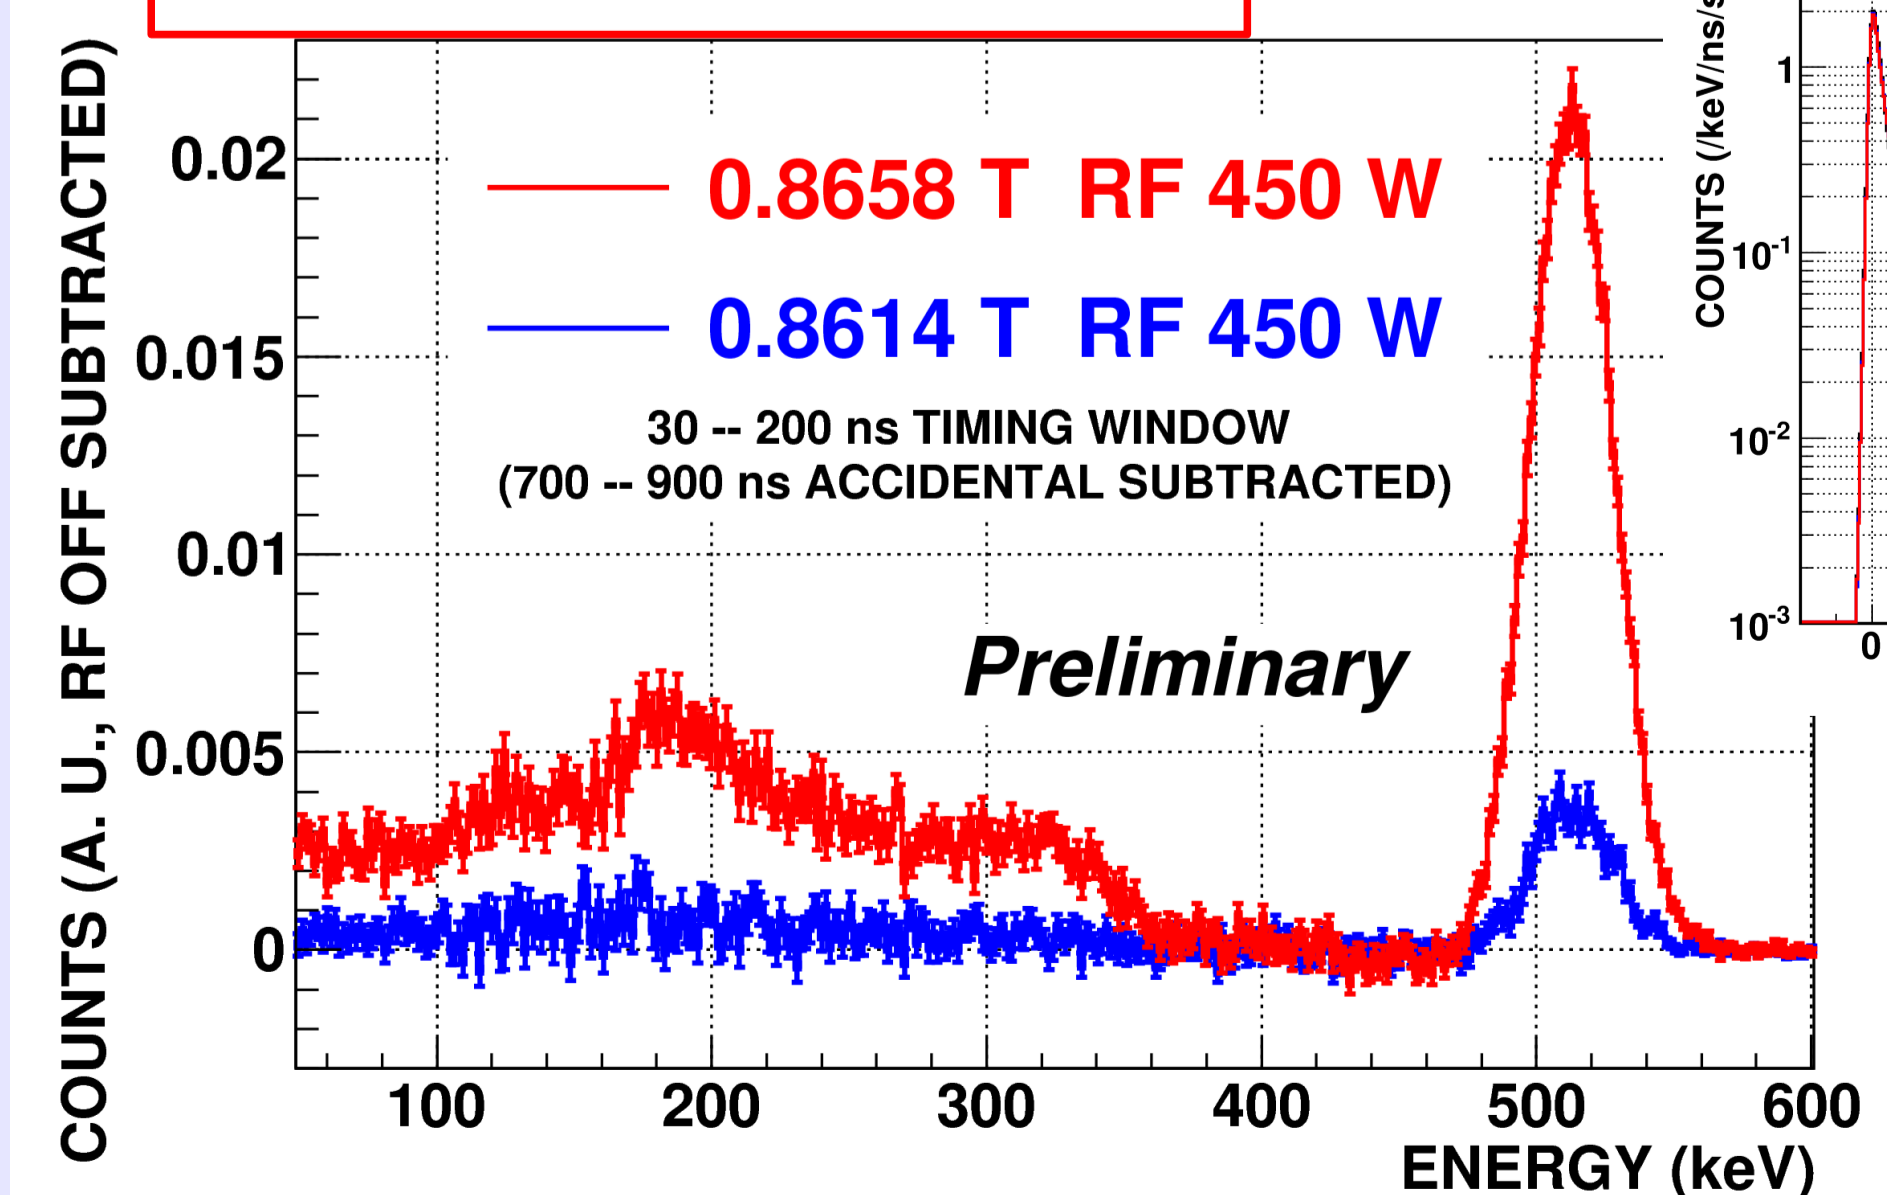

<sup>22</sup>Na source  
(700 kBq)

Inside of the  
RF cavity

## Current status

### Preliminary plots

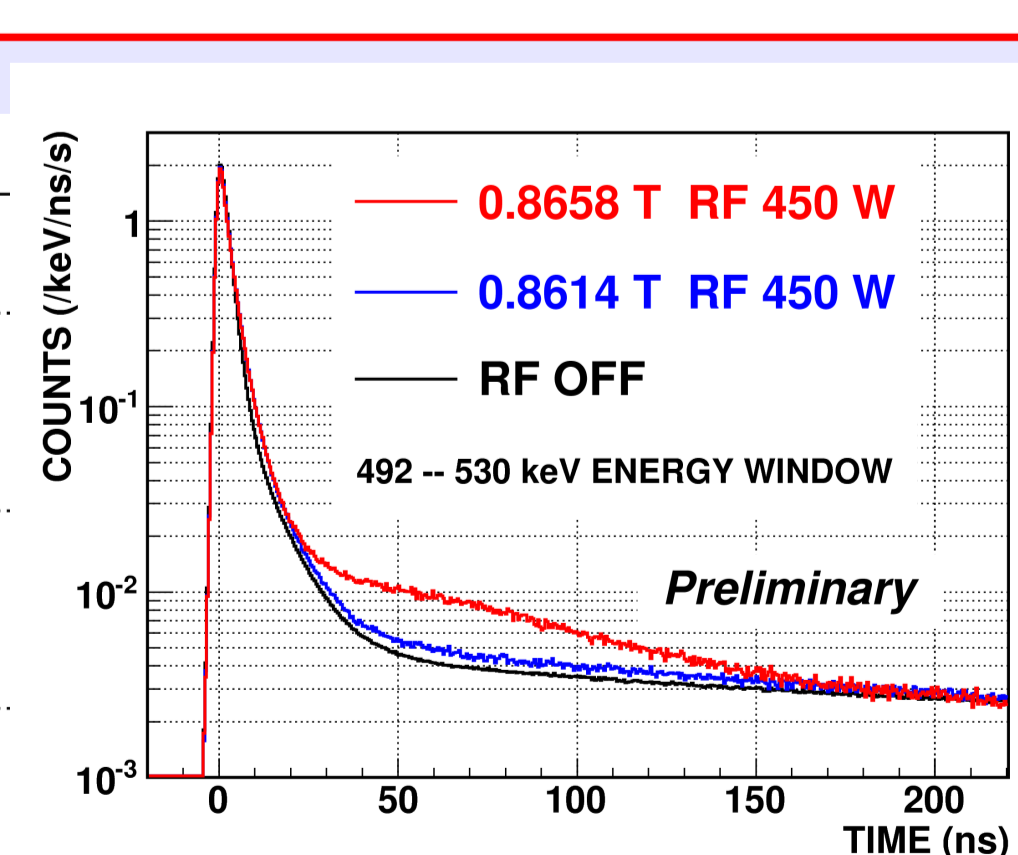

#### ENERGY SPECTRA

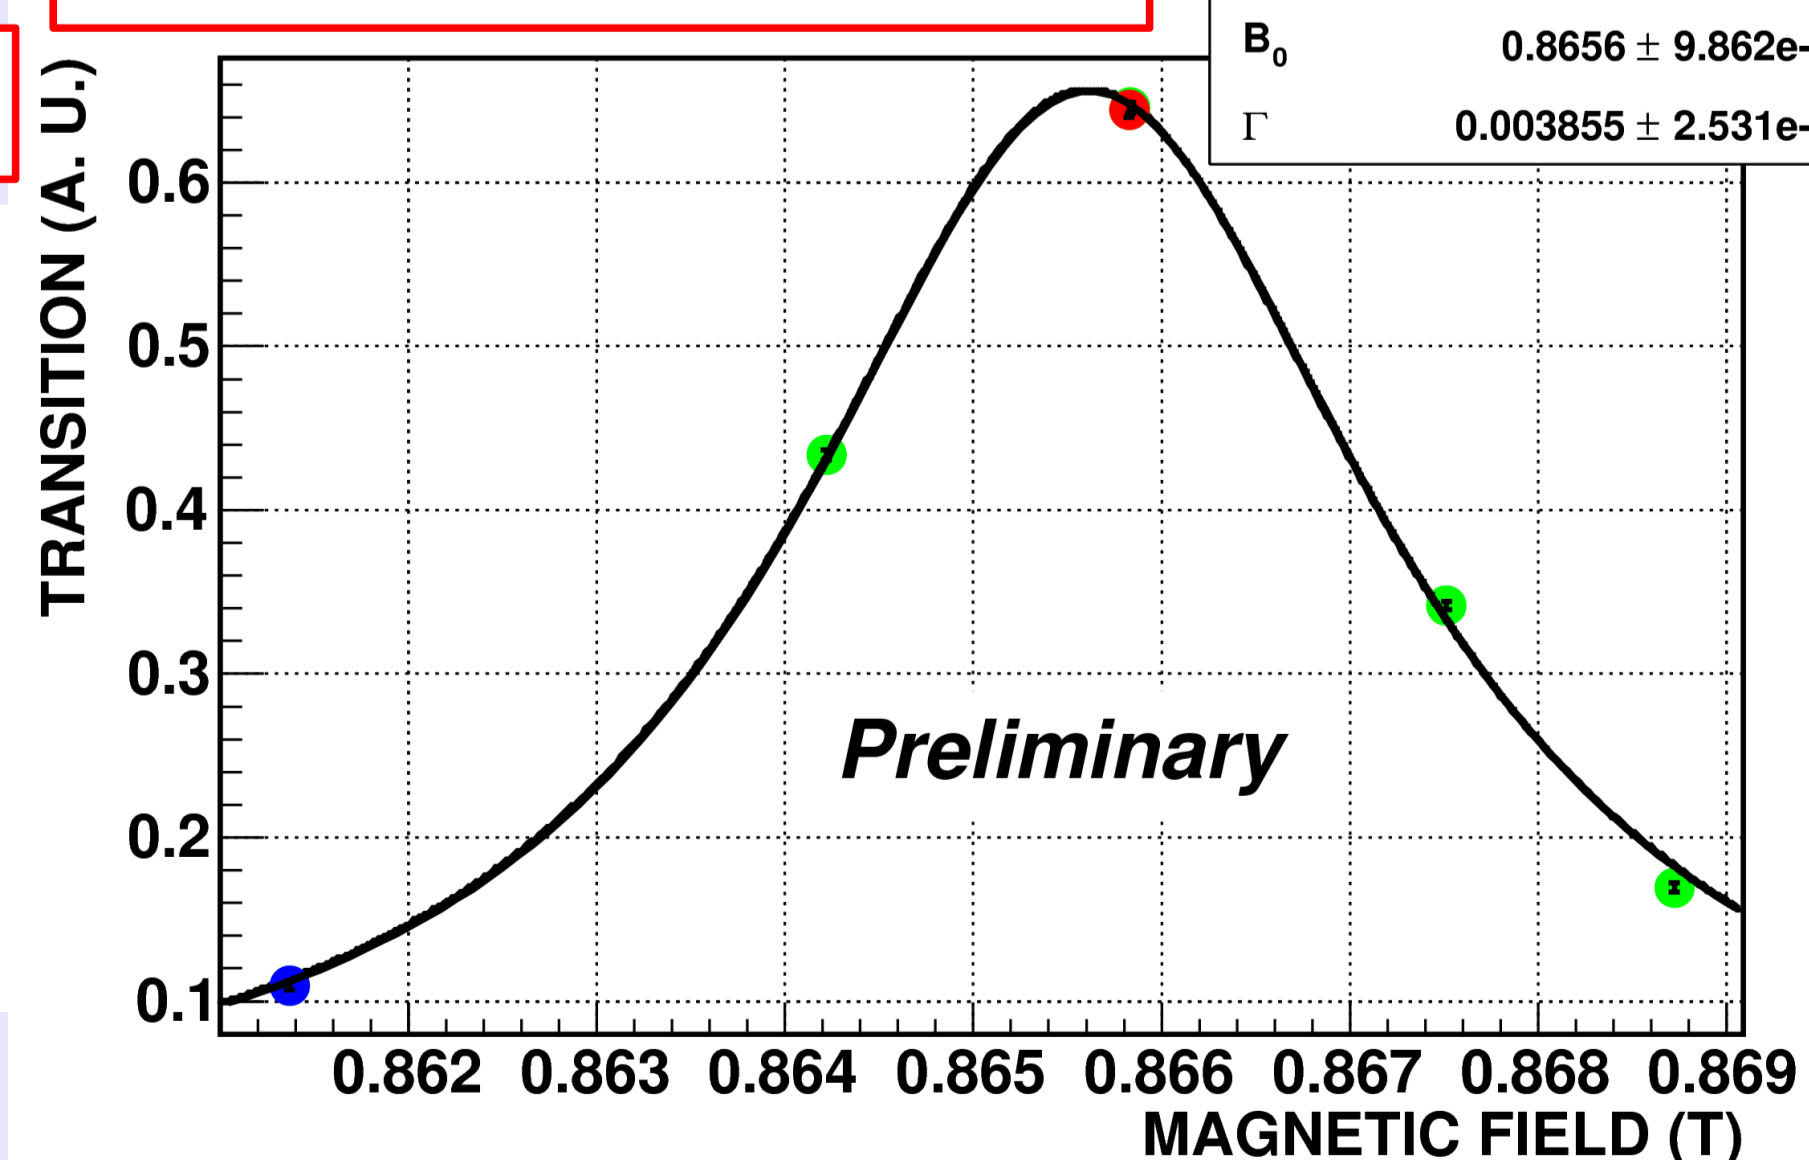

2  $\gamma$  decay rate increases because of the transition between o-Ps'  $m_z=0$  and  $m_z=\pm 1$  states.

We are presently taking more data....

#### TIMING SPECTRA

#### RESONANCE CURVE

Converted HFS value (from an **only 2 weeks run**) is  
**203.399**

**$\pm 0.005$  (23 ppm, stat.)**

**$\pm 0.029$  (140 ppm, sys.) GHz (Preliminary)**

(consistent with the previous experiments)  
The systematic error mainly comes from the non-uniformity of the magnetic field.

## Our goal

**O(1) ppm accuracy in a year**

1. Develop compensation coils  
 $\rightarrow$  Get **O(1) ppm B-uniformity**

2. Precisely measure the thermalization function.
3. **Derive the HFS value at O(1) ppm accuracy.**

$\rightarrow$  **Solve or Confirm the discrepancy between the experimental values and the theoretical value.**
